

# Project 2

## Approach

After starting this project and looking through the skeleton code and summary of grammar rules in this language of expression, it initially seemed like a manageable task. It wasn't as easy as I had assumed, as I soon discovered. It took longer than I had hoped to download Visual Studio and all of the C++ dependencies. Apart from setting up the environment, implementing the new functions was not too difficult; the proper formatting of the input presented a challenge. I had to pay close attention to each and every space, paren, and comma. My program would not display any errors if I had missed any of these. Aside from this little inconvenience, I liked working with conditional statements by handling the ternary and quaternary operators.

I was guided by examples, such as the plus and minus functions. Without them as a baseline for how the program was meant to handle various operations, I'm not sure I could write everything from scratch. I modified the parser to support additional operators, such as multiplication, negations (~), and some user-defined operators like average (&), maximum (>), and minimum (<). The program would handle more complex input scenarios if the variable token was modified to include underscores and the literals were changed to accept floating-point values.

## Test Plan

Test Purpose	Input	Expected Output	Actual Output
Unary expression	$((a + 4) \sim)$ , $a = 3$ ;	7	Correct
Binary expression	$((x * 2.6) + (y - 3))$ , $x = 1.5$ , $y = 2.4$ ;	3.3	Correct
Ternary expression	$(f ? 1 \ 2)$ , $f = 0$ ;	2	Correct
Quaternary expression	$(g \# 1 \ 2 \ 3)$ , $g = 2$ ;	3	Correct
Variable with underscore	$((7 / z\_1) + (z\_1 ^ 2))$ , $z\_1 = 2$ ;	7.5	Correct
Uninitialized variable	$(tt + ss)$ , $tt = 2$ ;	Error for ss	Error message

Duplicate assignment	(aa + 1), aa = 1, aa = 2;	Error for reassigning aa	Error message
----------------------	---------------------------	--------------------------	---------------

```

C:\Users\vadym\OneDrive x + v
((a + 4) ~), a = 3; Value = -7
((x * 2.6) + (y - 3)), x = 1.5, y = 2.4; Value = 3.3
(( 7 / z_1) + (z_1 ^ 2)), z_1 = 2; Value = 7.5
((6 % b) < 5), b = 4; Value = 1
(c > d), c = 9, d = 7; Value = 1
(e & 8), e = 5; Value = 6.5
(f ? 1 2), f = 0; Value = 2
(g # 1 2 3), g = 2; Value = 3
(tt + ss), tt = 2; ERROR: Variable is not assigned.
(aa + 1), aa = 1, aa = 2; ERROR: Variable is already assigned.
Press any key to continue . . . |

```

## Lessons Learned

After I struggled with the setup, it started to make a little more sense. Once I got past that, the logic just flowed. In this project, I have gained a lot about handling recursive parsers and symbol tables. Working with custom operators was enjoyable and somewhat challenging, especially since they weren't your typical relational operators. In this project, I would enhance the error-processing engine to generate more detailed feedback. Overall, this project was a successful learning experience, despite certain challenges encountered.
